

# ETC3580: Advanced Statistical Modelling

Week 5: Count responses

#### **Outline**

- 1 Poisson regression
- 2 Quasi-Poisson regression
- 3 Negative binomial regression
- 4 Zero inflated count models

#### **Poisson distribution**

Let *Y* = number of events in given time interval. If events independent, and prob of event proportional to length of interval, then *Y* is Poisson distributed.

#### Poisson( $\mu$ ) distribution

$$P(Y = y) = \frac{e^{-\mu}\mu^{y}}{y!}$$

- $E(Y) = Var(Y) = \mu$
- If Y  $\sim$  B(n, p), then Y  $\approx$  Poisson(np) for small p/n.
- If Y ~ Poisson( $\mu$ ), then Y  $\approx$  N( $\mu$ ,  $\mu$ ) for large  $\mu$ .
- Poisson( $\mu_1$ ) + Poisson( $\mu_1$ )  $\sim$  Poisson( $\mu_1 + \mu_2$ ).

## **Poisson distribution**

### Regression with count data

Suppose response Y is a count (0,1,2,...).

- If count is bounded and bound is small, use binomial regression.
- If min count is large, use normal approximation.
- Otherwise, use Poisson or negative binomial.

$$y_i \sim \text{Poisson}(\mu_i)$$
  
 $\log(\mu_i) = \eta_i = \beta_0 + \beta_1 x_{i,1} + \dots + \beta_q x_{i,q}$ 

Log link function forces positive mean.

$$y_i \sim \text{Poisson}(\mu_i)$$
  
 $\log(\mu_i) = \eta_i = \beta_0 + \beta_1 x_{i,1} + \dots + \beta_q x_{i,q}$ 

- Log link function forces positive mean.
- Likelihood:  $L = \prod_{i=1}^{n} \frac{\exp^{-\mu_i} \mu_i^{y_i}}{y_i!}$

$$y_i \sim \text{Poisson}(\mu_i)$$
  
 $\log(\mu_i) = \eta_i = \beta_0 + \beta_1 x_{i,1} + \dots + \beta_q x_{i,q}$ 

Log link function forces positive mean.

Likelihood: 
$$L = \prod_{i=1}^{n} \frac{\exp^{-\mu_i} \mu_i^{y_i}}{y_i!}$$
$$\log L = \sum_{i=1}^{n} \left[ -\mu_i + y_i \log(\mu_i) - \log(y_i!) \right]$$
$$= \sum_{i=1}^{n} \left[ -\exp(\mathbf{x}_i'\beta) + y_i\mathbf{x}_i'\beta - \log(y_i!) \right]$$

6

$$y_i \sim \text{Poisson}(\mu_i)$$
  
 $\log(\mu_i) = \eta_i = \beta_0 + \beta_1 x_{i,1} + \dots + \beta_q x_{i,q}$ 

- Log link function forces positive mean.
- Likelihood:  $L = \prod_{i=1}^{n} \frac{\exp^{-\mu_i} \mu_i^{y_i}}{y_i!}$  $\log L = \sum_{i=1}^{n} \left[ -\mu_i + y_i \log(\mu_i) \log(y_i!) \right]$  $= \sum_{i=1}^{n} \left[ -\exp(\mathbf{x}_i'\beta) + y_i\mathbf{x}_i'\beta \log(y_i!) \right]$

#### Deviance

$$D = -2 \log L = -2 \sum_{i=1}^{n} \left[ -\hat{\mu}_i + y_i \log(\hat{\mu}_i) - \log(y_i!) \right]$$
$$= 2 \sum_{i=1}^{n} (y_i \log(y_i/\hat{\mu}_i) - (y_i - \hat{\mu}_i))$$

#### **Deviance**

$$D = -2 \log L = -2 \sum_{i=1}^{n} \left[ -\hat{\mu}_i + y_i \log(\hat{\mu}_i) - \log(y_i!) \right]$$
$$= 2 \sum_{i=1}^{n} (y_i \log(y_i/\hat{\mu}_i) - (y_i - \hat{\mu}_i))$$

- Check distributional assumptions by comparing D against  $\chi^2$
- Compare changes in deviance using a  $\chi^2$  test as for binomial regression.
- Use profile likelihood to find confidence intervals for parameters.
- Common for a model to be "over-dispersed".

## **Dispersed Poisson model**

When model is over-dispersed (variance too large):

- estimates of  $\beta$  consistent, but standard errors incorrect.
- could correct model using quasi-Poisson model or negative binomial model.

#### **Outline**

- 1 Poisson regression
- 2 Quasi-Poisson regression
- 3 Negative binomial regression
- 4 Zero inflated count models

## **Quasi-Poisson models**

```
fit <- glm(y ~ x1 + x2,
  family='quasipoisson', data)</pre>
```

- Use F-tests not  $\chi^2$  tests when using quasi-Poisson models
- Overdispersion parameter represents the variance inflation

#### **Outline**

- 1 Poisson regression
- 2 Quasi-Poisson regression
- 3 Negative binomial regression
- 4 Zero inflated count models

## **Negative binomial distribution**

In series of independent trials, each with prob *p* of success, let *Z* be number of trials until *k*th success.

$$P(Z = z) = {z - 1 \choose k - 1} p^k (1 - p)^{z - k}, z = k, k + 1, ...$$

- $\blacksquare$  k = 1 gives the *geometric* distribution.
- The NegBin distribution also arises when  $Y \sim \text{Poisson}(\lambda)$  and  $\lambda \theta \sim \gamma$  for some constant  $\theta$ .
- For negative binomial regression, we model Y = Z k.
- **E**(Y) =  $\mu = k(1 p)/p$  and Var(Y) =  $\mu + \mu^2/k$ .
- $p = k/(k + \mu)$

# **Negative binomial regression**

$$Y_i \sim \text{NegBin} - k \text{ with mean } \mu_i \text{ and variance } \mu_i + \mu_i^2/k.$$

$$\eta_i = \log\left(\frac{\mu_i}{\mu_i + k}\right) = \beta_0 + \beta_1 x_{i,1} + \dots + \beta_q x_{i,q}$$

k (the "dispersion" parameter) is usually estimated along with the coefficients by MLE:

$$L = \prod_{i=1}^{n} {y_i + k - 1 \choose k - 1} p_i^k (1 - p_i)^{y_i}$$

$$\log L = \sum_{i=1}^{n} \left( y_i \log \left( \frac{\mu_i}{\mu_i + k} \right) - k \log(1 + \mu_i/k) + \sum_{i=1}^{y_i - 1} \log(i + k) - \log(y_i!) \right)$$

## **Negative binomial regression**

```
fit <- glm(y ~ x1 + x2,
  family=negative.binomial(k), data)

fit <- MASS::glm.nb(y ~ x1 + x2, data)</pre>
```

#### **Outline**

- 1 Poisson regression
- 2 Quasi-Poisson regression
- 3 Negative binomial regression
- 4 Zero inflated count models

#### **Zero inflated count models**

#### **Examples of zero-inflated data:**

- Number of insurance claims for each account
- Number of arrests for criminal offences for each individual
- Number of articles written by PhD students Over-dispersed models do not deal adequately with this type of data.

#### Zero-inflated count models

#### Solution 1: Hurdle model

- Model for probability of zero (logistic).
- Model for non-zero counts (truncated Poisson). P(Y = 0) = p

$$P(Y = j) = \frac{1 - p}{1 - f(0)}f(j), \qquad j > 0$$

- p is probability of zero; f is Poisson probability.
- Two sets of coefficients for the two parts of the model.

```
fit <- pscl::hurdle(y ~ x1 + x2, data)</pre>
```

#### **Zero-inflated count models**

#### Solution 2: Mixture model

- Model for probability of always zero (logistic).
- Model for counts (regular Poisson). P(Y = 0) = p + (1 - p)f(0)

$$P(Y = j) = (1 - p)f(j), j > 0$$

- p is probability of zero; f is Poisson probability.
- Two sets of coefficients for the two parts of the model.

```
fit <- pscl::zeroinfl(y ~ x1 + x2, data)</pre>
```

#### **Zero-inflated count models**

- Often difficult to select between these what makes most sense for the application?
- Can have different predictors for the two sub-models:

```
fit <- zeroinfl(y ~ x1 + x2 | x3, data) count model before the | and zero model after.
```
